

**CN-SIM:**  
A qualitative comparison  
of PAUSE, BCN(0,0),  
and BCN-Max

**Davide Bergamasco**

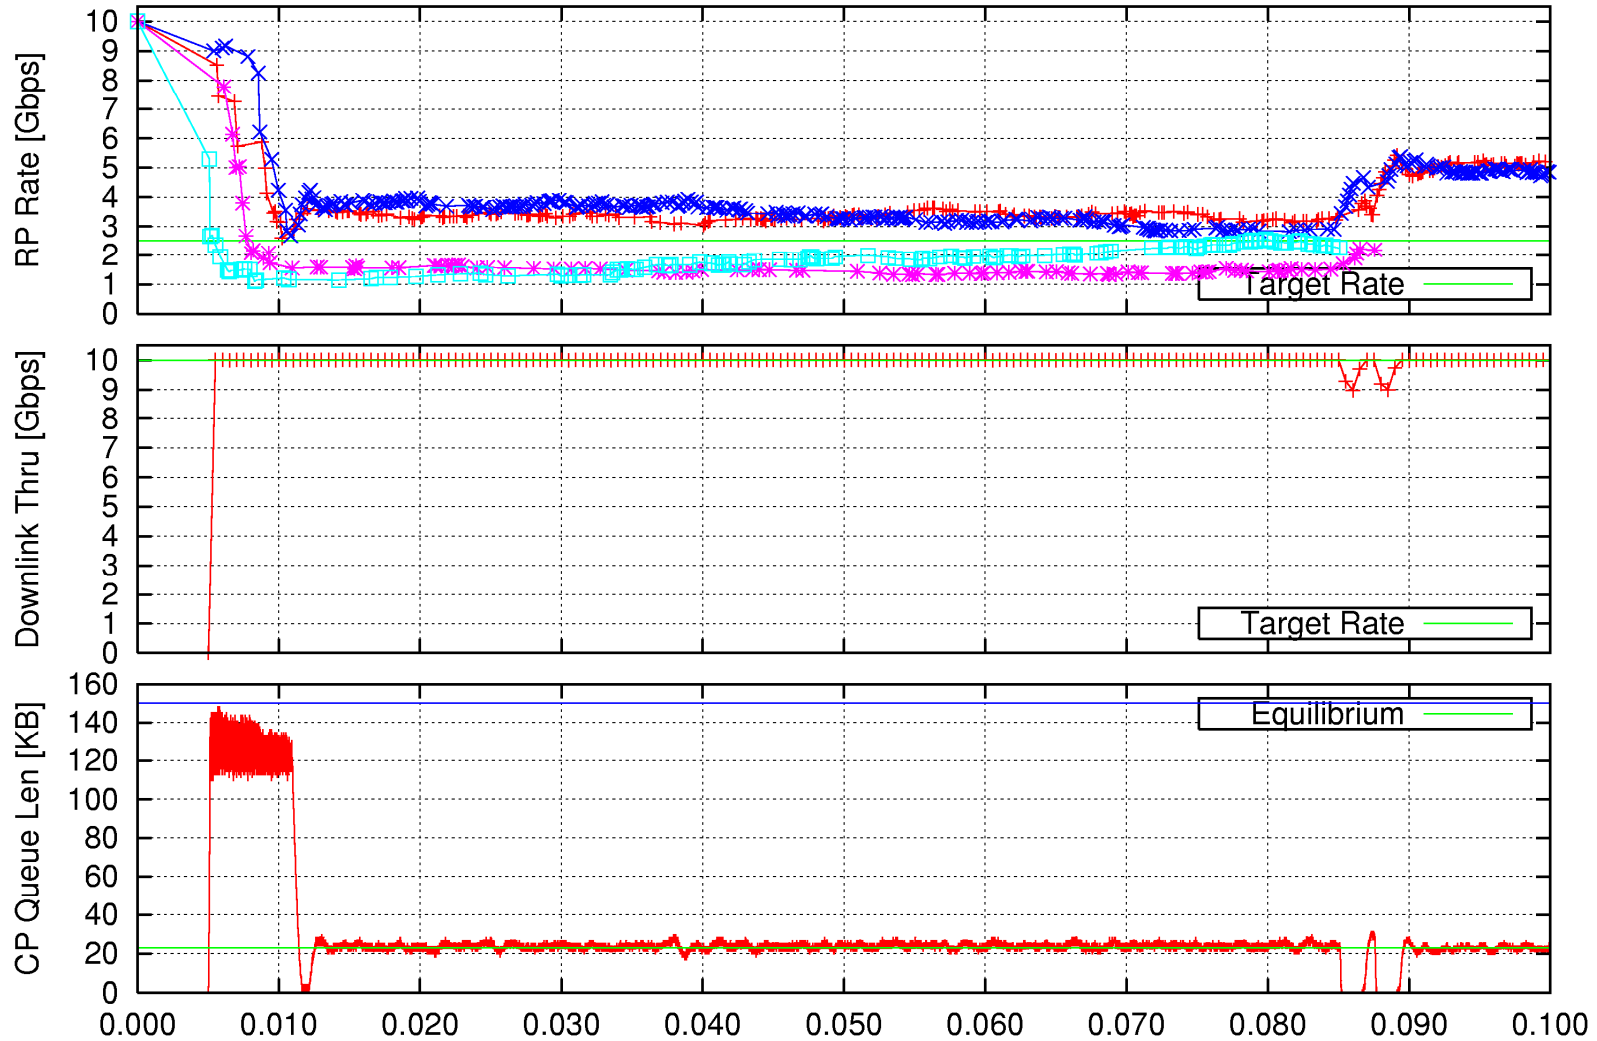

# Objective

- Compare from a purely qualitative standpoint the following mechanisms:
  - Pause
  - Pause + BCN(0,0)
  - Pause + BCN-Max
- Simulation Environment
  - Topology, workload, configuration, and parameters as per Baseline Simulation Scenario

# Pause and Pause + BCN(0,0)

- Both mechanisms have already been defined and studied in the Baseline Simulation Scenario
- Simulation results are repeated in this document for ease of comparison

# Pause

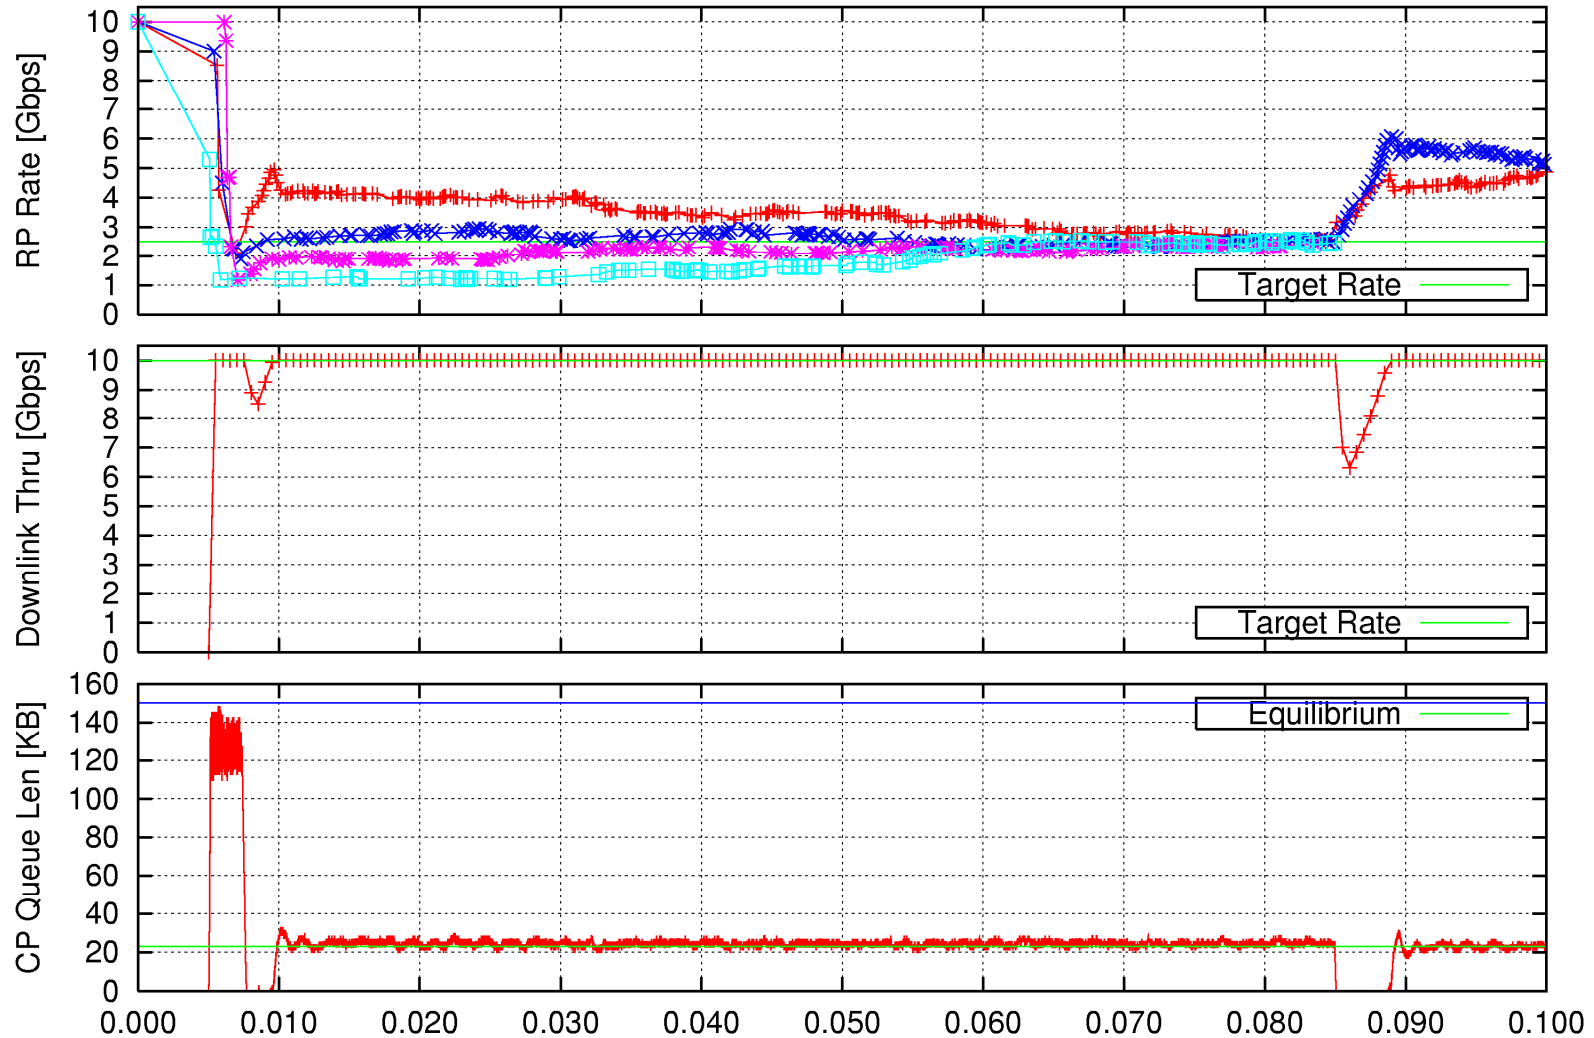

# Pause + BCN(0,0)

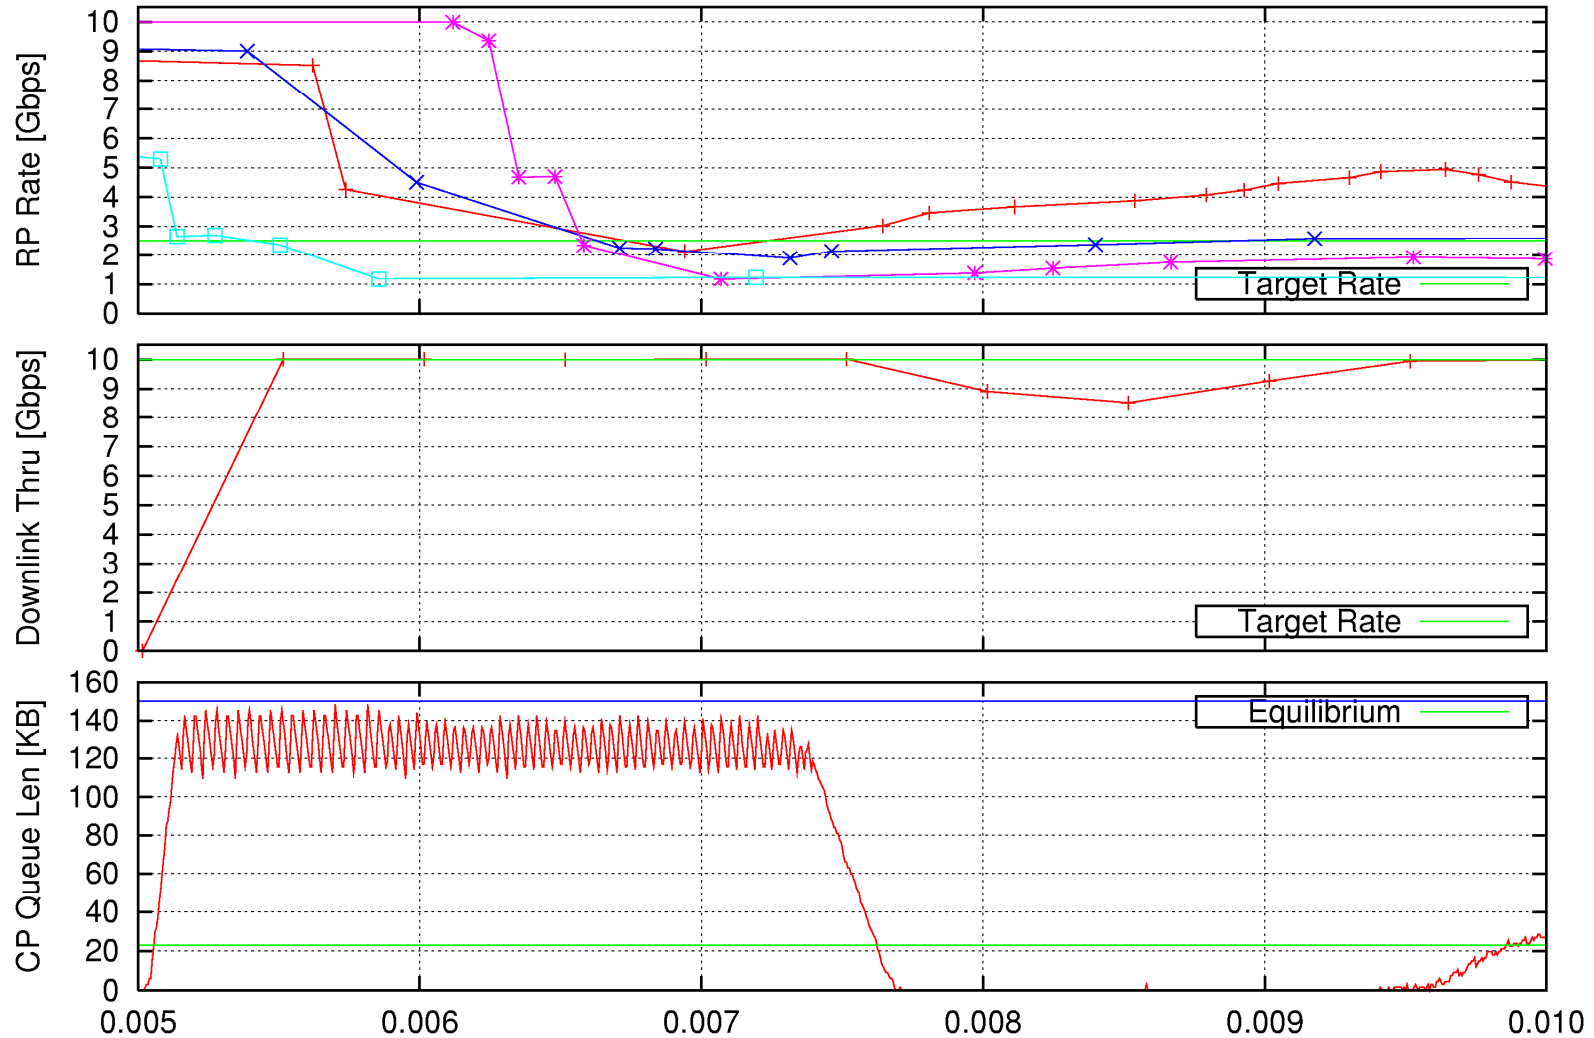

# BCN-Max (Maximum negative feedback)

- Two flavors of BCN-Max
  - 1) When pause is asserted, turn any BCN(x,y) generated into the maximum negative feedback BCN(Qeq, 2\*Qeq)
  - 2) Just like BCN(0,0) (i.e., trigger based on Qsc), but instead of sending BCN(0,0) send BCN(Qeq, 2\*Qeq)
- Settings
  - BCN(0,0) disabled

# BCN-Max #1 (Pause-based)

# BCN-Max #1 (Pause-based)

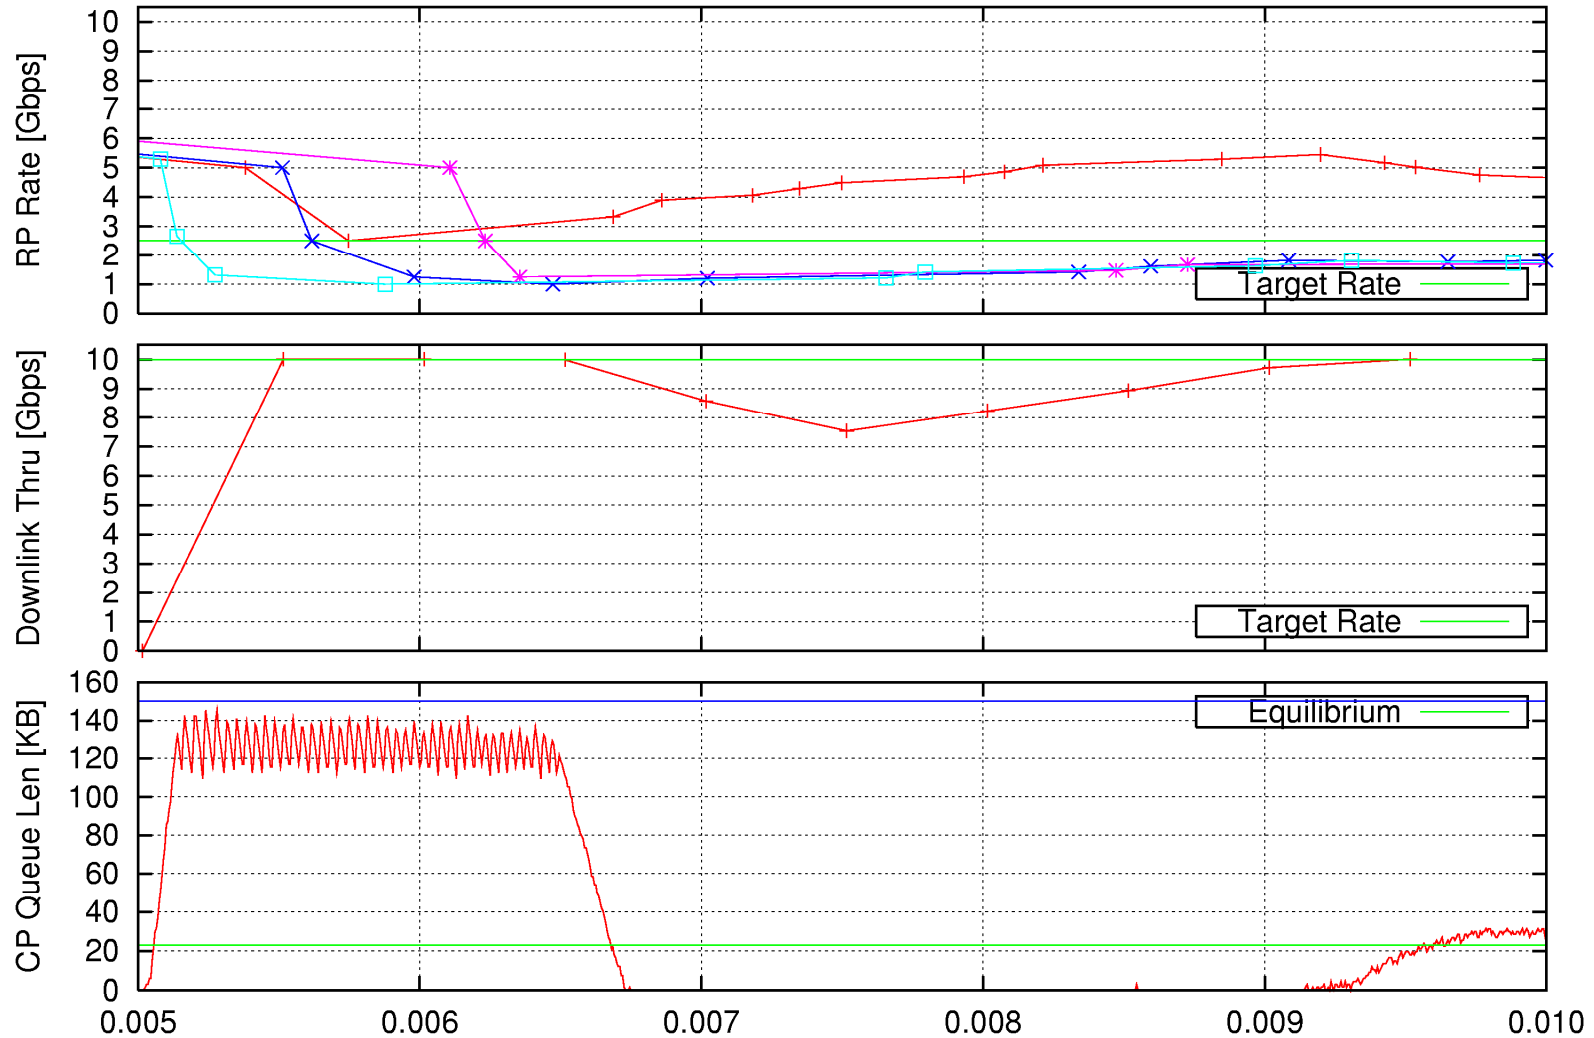

# BCN-Max #2 (Qsc-based)

# BCN-Max #2 (Qsc-based)

# Speeding up positive transient response

- Even with BCN-Max response to positive transients still seems a bit slow
- This is due to the fixed (and low) sampling rate
- What if the sampling rate is increased during BCN-Max generation?
- Let's try to reduce the sampling interval by a scale factor  $S$  (e.g. 8) when  $Q_{len} > Q_{sc}$

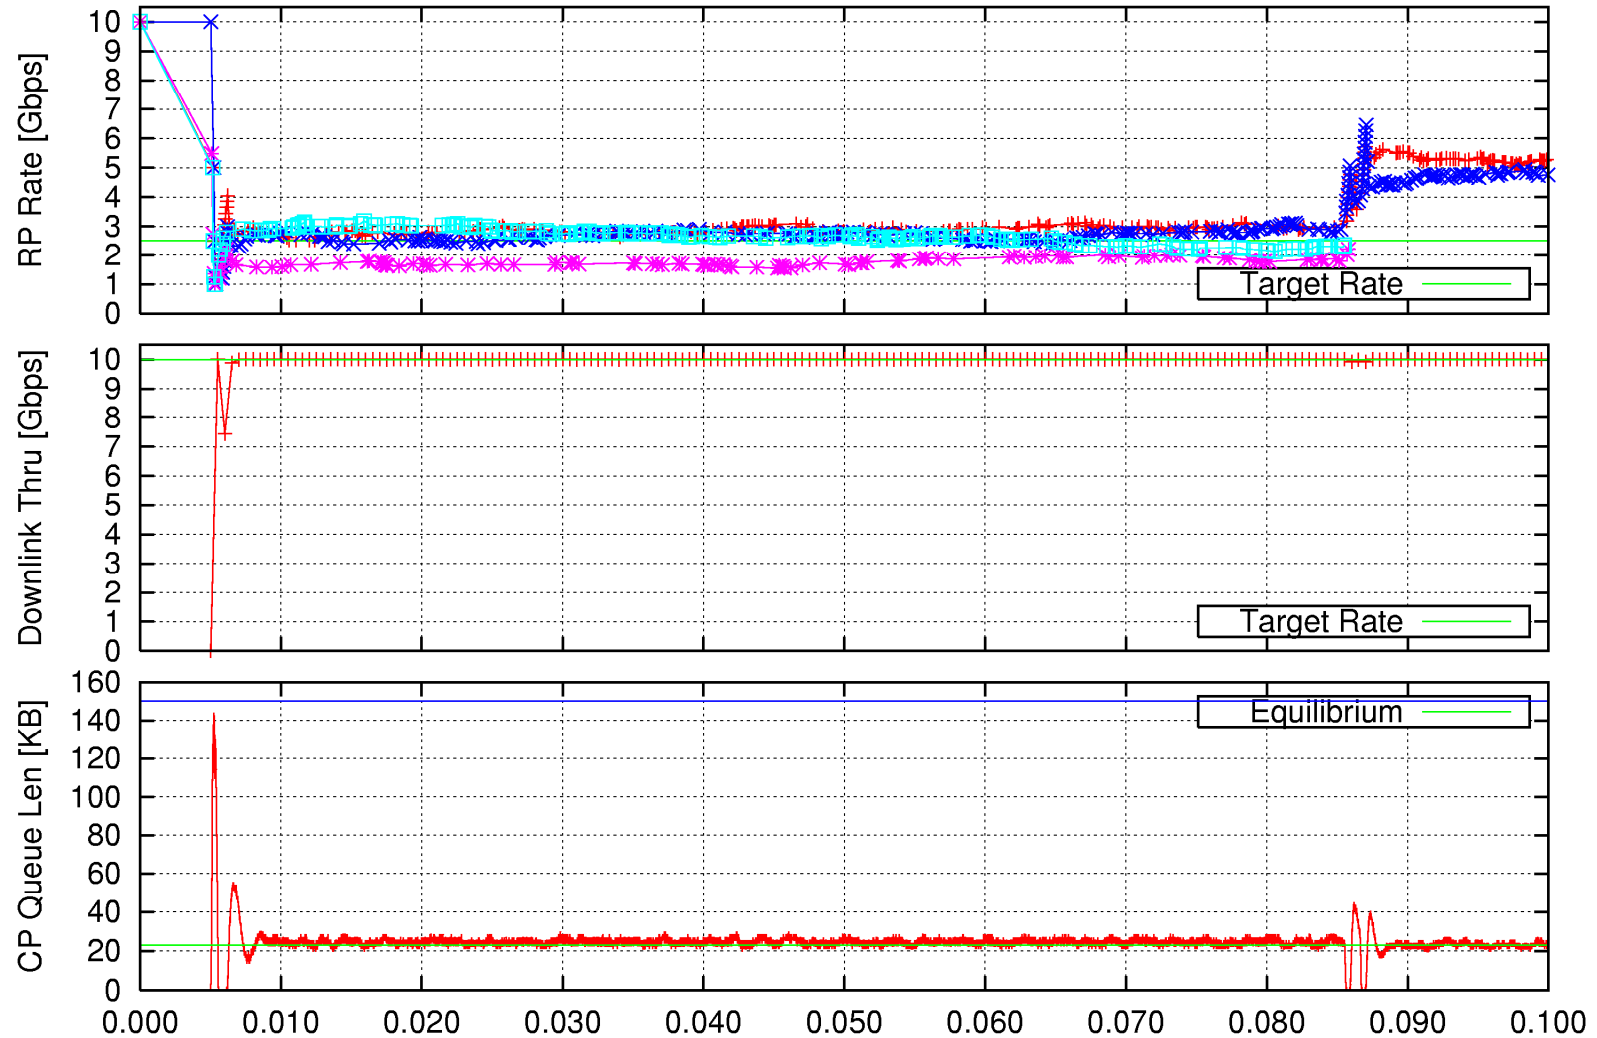

# BCN-Max + Over-sampling if $Q_{len} > Q_{sc}$

# Speeding up negative transient response

- We have sped up the response to the positive edge of a transient
- Throughput suffers because the response to the negative edge of a transient is not as fast
- Let's try to increase the sampling rate by the same amount also when  $Q_{len} == 0$

# BCN-Max + Over-sampling if $Q_{len} > Q_{sc}$ or $Q_{len} == 0$

# Speeding up transient response further

- Now we have sped up the response to both positive and negative transients
- Let's try to make the system symmetrical by introducing BCN+Max
- When  $Q_{len} == 0$  turn any  $BCN(x,y)$  into  $BCN(-Q_{eq}, -2*Q_{eq})$ , i.e., the maximum positive feedback

# BCN-Max + BCN+Max + Over-sampling if $Q_{len} > Q_{sc}$ or $Q_{len} == 0$

# Conclusions

- BCN-Max based on Qsc shows a better and more consistent behavior than BCN-Max based on Pause assertion
- Transient responsiveness can be improved by increasing sampling rate during transient
- Don't discount BCN(0,0) yet!
  - There may be situations where it is the only viable solution
