Overview

This slide deck (dd-chen-RAP-ATS-0619-v02), as an individual contribution of the editors, discusses how the P802.1Qdd Resource Allocation Protocol (RAP) can support dynamic reservations for streams using the P802.1Qcr Asynchronous Traffic Shaping (ATS).

Leveraging the ATS latency math described in the Annex X of P802.1Qcr/D1.0, this deck shows a stream admission control scheme as an example of how to achieve bounded latency and zero congestion loss for dynamic stream establishment using RAP.

To enable accurate calculation of per-hop delay and buffer requirements on each bridge, e.g. by taking account of clock deviations, the needed information to be carried in the reservation attributes is also investigated.
Key Features of ATS

- Asynchronous operation independent of clock synchronization
  - the timing of frames determined based on local clocks
  - taken inter-device clock rate deviations into account for calculation of latency bounds
- Per-stream reshaping combined with per-class queuing (aka. interleaved shaping)
  - eliminating the burstiness cascade effect of per-class shaping (e.g. CBS)
  - end-to-end latency decomposed into topology-independent per-hop latency bound
  - providing protection against babbling idiots through integrated accurate policing
- Traffic characterization using Token Bucket model
  - traffic specification decoupled from the class measurement interval
  - allowing use of arbitrary transmission period for each stream, i.e. per-stream interval
- Applicable for both static and dynamic stream establishment
  - The use of ATS for static cases is analyzed in the paper [1].
  - This presentation focuses on use of the 802.1Qdd-RAP for dynamic cases.

ATS Latency Math in P802.1Qcr/D1.0

The latency decomposition model for ATS described in Annex X of P802.1Qcr/D1.0

- **Delay bound at k\textsuperscript{th} hop for stream f:**
  - \( d_{BU,max}(k, f) \), the max buffering delay, is calculated using the detailed information of all streams to be transmitted at \( B_k \).
  - The other per-hop delay components are stream independent and can be derived from the bridge parameters.

- **End-2-End delay bound for stream f:**

\[
d_{max}(k, f) = d_{AT,max}(k) + d_{PR,max}(k) + d_{BU,max}(k, f) + d_{MD,max}(k)
\]

\[
d_{BU,max}(k, f) = \max_{h \in F_A(k, f)} b_{max}(k, g) - l_{min}(h) + l_{LP,max}(k, h) + \frac{l_{min}(h)}{R(k)}
\]

\[
d_{max}(f) = \sum_{k=1}^{n} d_{BU,max}(k, f) + \sum_{k=1}^{n} d_{MD,max}(k) + \sum_{k=2}^{n} d_{AT,max}(k) + \sum_{k=2}^{n} d_{PR,max}(k)
\]
Dynamic Stream Admission for ATS

- **Assumptions**
  - Information is limited to devices and streams along the path from talkers to listeners
  - Only the per-class parameters are configured via management
    - e.g. max. reservable bandwidth and max. per-hop delay bound of each ATS SRclass
  - Streams are established under the control of a stream reservation protocol

- **Per-hop delay bound**
  - a per-class per-port parameter, added to accumulated latency for all the streams associated with the same SRclass
  - not the maximum calculated over the currently reserved streams
  - but the upper bound value that limits the number of streams reservable under the bandwidth and resources constraints

- **Stream admission control**
  executed by the reservation protocol for each stream reservation request to check whether adding this stream meets the following constraints on each bridge along the path
  - **Bandwidth constraints**: not exceeding the maximum reservable bandwidth
  - **Latency constraints**: not exceeding the per-hop delay bound
  - **Resource constraints**: not exceeding the available resources, e.g. queuing buffers, FDB, shaper FSMs, etc.

A stream can be admitted only when it meets all these constraints on all bridges along the path.
Example Dynamic Admission Scheme for ATS

- **Per-class per-port** parameters set by management
  
  Assume one or more SRclasses associated with ATS, each denoted as *ClassX*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdminMaxPerHopDelay</td>
<td>Max. per-hop delay</td>
<td>$D_{\text{max}}(k, \text{ClassX})$</td>
</tr>
<tr>
<td>MaxAvailableBandwidth *</td>
<td>Max. reservable bandwidth (in % of port tran. rate)</td>
<td>$R_{\text{max}}(k, \text{ClassX})$</td>
</tr>
<tr>
<td>MaxInterferingSize</td>
<td>Max. size of an interfering frame</td>
<td>$L_{\text{LP, max}}(k)$</td>
</tr>
</tbody>
</table>

* e.g., by use of the *deltaBandwidth* and *lockClassBandwidth* managed objects specified in Clause 34 FQTSS

- **Per-stream** parameters used for admission control and resource allocation on the bridge at $k^{\text{th}}$ hop

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>CommittedBurstSize</td>
<td>Max. burst size</td>
<td>$b_{\text{max}}(k, f)$</td>
</tr>
<tr>
<td>CommittedInformationRate</td>
<td>Max. information rate</td>
<td>$r_{\text{max}}(k, f)$</td>
</tr>
<tr>
<td>MaxFrameSize</td>
<td>Max. frame length</td>
<td>$l_{\text{max}}(k, f)$</td>
</tr>
<tr>
<td>MinFrameSize</td>
<td>Min. frame length</td>
<td>$l_{\text{min}}(k, f)$</td>
</tr>
</tbody>
</table>

**Note:** In the process of stream reservation, these per-stream parameters need to be recalculated at each hop along the stream path, by taking into account the bridge’s media-dependent overheads and local clock deviations. *(See TSpec discussion later)*
Example Dynamic Admission Scheme for ATS (Cont.)

- **Local routines for admission control** of a stream \( f \) transmitted with the SRclassX on the \( k \)th hop
  - Determine the stream parameters \( [b_{\text{max}}(k, f), r_{\text{max}}(k, f), l_{\text{max}}(k, f), l_{\text{min}}(k, f)] \)
  - Check **bandwidth constraints** with \( r_{\text{max}}(k, f) \leq \text{currentAvailableBandwidth}(k, \text{ClassX}) \)
  - Check **latency constraints** with \( d_{\text{max}}(k, f) \leq D_{\text{max}}(k, \text{ClassX}) \)
    - while \( d_{\text{max}}(k, f) \) is the maximum per-hop delay calculated for stream \( f \) and all currently reserved streams by using the ATS latency math for the per-hop delay bound described in Annex X of P802.1Qcr/D1.0

\[
d_{\text{max}}(k, f) = d_{\text{AT,\text{max}}}(k) + d_{\text{PR,\text{max}}}(k) + d_{\text{MD,\text{max}}}(k) + d_{\text{BU,\text{max}}}(k, f)
\]

- **Check resource constraints**
  - \( b_{\text{max}}(k, f) \) and \( l_{\text{max}}(k, f) \) could be used as input for calculation of the buffer sizes required by stream \( f \)
  - However, the algorithm used for calculation of available resources for a stream e.g. the queuing buffer, strongly depends on bridge implementation.
Traffic Specification for ATS (1)

- Recap: SRP TSpec for AV streams using CBS
  - using the triple $\{\text{MaxFrameSize}, \text{MaxFramesPerInterval}, \text{classMeasurementInterval}\}$
  - defined by a Talker, specifying the traffic shape output from the Talker
  - propagated unchanged by bridges to Listener(s)

- Requirements on TSpec for streams using ATS
  - not restricted to use of the interval-based pattern
  - support for a more general traffic pattern described by talkers using token bucket parameters $(b,r)$
  - taking account of changes in traffic characteristics at each hop, e.g. caused by clock deviations

- Suggested TSpec parameters for ATS (cmp. P802.1Qcr/D1.0 Annex X)
  - $\text{CommittedInformationRate}$: Reflects the $\text{CommittedInformationRate}$ parameter, but accounts for local async. Clock rate inaccuracies during propagation
  - $\text{CommittedBurstSize}$: Reflects the $\text{CommittedBurstSize}$ parameter
  - $\text{MinFrameSize}, \text{MaxFrameSize}$: Frame size bounds
Traffic Specification for ATS (2)

- **Propagation of CommittedInformationRate** from Talker to Listener
  - At the $k^{th}$ hop, $\text{CommittedInformationRate}$ is a function of the same parameter at the prev. hop and the ClockRateDeviationMax parameters of both adjacent devices:

$$\text{CommittedInformationRate} \left( k, f \right) = \frac{1}{1 - 10^{-6}\text{ClockRateDeviationMax}(k)} \times \text{CommittedInformationRate} \left( k - 1, f \right) \left( 1 + 10^{-6}\text{ClockRateDeviationMax}(k - 1) \right)$$

- **Interoperability with AVB end-stations**
  - An example of converting MSRPv0 TSpecs of AV streams to ATS TSpecs for transmission with ATS in the network.

$$\text{CommittedBurstSize} \left( 1, f \right) = \text{MaxFramesPerInterval}(f) \times (\text{MaxFrameSize}(f) + \text{portMediaDependentOverhead}(1)) \times 8$$

$$\text{CommittedInformationRate} \left( 1, f \right) = \frac{\text{MaxFramesPerInterval}(f) \times (\text{MaxFrameSize}(f) + \text{portMediaDependentOverhead}(1)) \times 8}{\text{Interval}(f)}$$

- **Changing frame lengths (work in progress)**
  - $\text{portMediaDependentOverhead}$ may vary along the path
  - Tags may be added or removed, e.g. redundancy Tag of 802.1CB
  - Solution space: from standardized bounds, bounds distributed by Talkers, ..., exact delay impact computation, with additional traffic characterization

Some Issues

- **Bridge local rules for admission control**
  - RAP may specify rules for checking bandwidth and latency constraints, but cannot specify how to check resource constraints, which strongly depends on bridge implementation.
  - RAP shall specify the managed objects required by local admission control, e.g. `AdminMaxPerHopDelay`.

- **TSpec** *(to be considered for use in RAP with support for CBS, ATS, CQF, etc)*
  - In RAP service interface primitives: support for both legacy and token bucket based description?
  - In Talker Advertise attributes: carrying only shaper-specific TSpec parameters, e.g. carrying legacy TSpec for CBS and carrying only token bucket parameters for ATS?

- **Interoperability of ATS network with AVB end-stations** *(support by RAP required?)*
  - AVB End stations using CBS and MSRP
  - An ATS/RAP network with MSRP running only at the edge ports
