Re:			
Abstract	We propose that 802.16.1 issue a Call for Contributions to collect input relevant to the power amplifier model to be used in physical layer simulations. This is an edited version of a document presented at IEEE 802.16 Session #7.5.		
Purpose	We request 802.16.1 to issue this Call for Contributions or a modified form of it.		
Notice	This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.		
Release	The contributor grants a free, irrevocable license to the IEEE to incorporate text contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.

CALL FOR CONTRIBUTIONS ON POWER AMPLIFIER MODEL PARAMETERS [PROPOSED]

IEEE 802.16.1 Session #8

Deadline: 7 July 2000

The IEEE 802.16 Working Group on Broadband Wireless Access is preparing to define the 802.16.1 broadband wireless access air interface specification in accordance the "Development Plan for the 802.16.1 Air Interface Standard" (Document IEEE 802.16-99/05). It has approved a proposal (Document IEEE 802.16.1pc-00/29r1) as the initial draft of the physical layer (PHY).

As the 802.16.1 Task Group revises and finalizes its specification, it is interested in validating its standard through simulation and possibly through measurement. One critical issue in the simulation of the PHY is the behavior of the power amplifier and its nonlinearity. This will require a specific model and a specific set of parameters representing typical power amplifiers (PAs) as might be used in implementations of the 802.16.1 standard.

This Call for Contributions invites contributions suggesting a PA model, along with specific parameter data representing typical base station and subscriber station PAs, for use in the system simulation. In addition, supporting measurements, as detailed below, are requested.

Contributions will be considered non-confidential and will be posted, as soon as possible following receipt, for public access on the 802.16 Web Site http://ieee802.org/16>.

Contributions will be considered only if submitted using Revision 8 or higher of the 802.16 Document Submission Template <<u>http://ieee802.org/16/docs/802_16_template.doc></u>. The template requires a cover page and a narrative. In the cover sheet category labeled "Re", please cite not only this document but also the document number of the document(s) you are addressing.

Email your contribution, for receipt by the deadline of 7 July 2000, to each of the following:

- 802.16 Chair Roger Marks <mailto:marks@nist.gov>
- 802.16.1 Chair Lou Olsen <mailto:louis.olsen@teligent.com>
- 802.16.1 PHY Chair Jay Klein <mailto:jay@ensemblecom.com>

Late submissions are subject to time constraints that may preclude full evaluation by the committee.

The PAs under consideration should meet the following specifications:

(1) Subscriber Station PA

This will be used with QPSK and a root-raised-cosine (RRC) filter with $\alpha = 0.15$ or 0.25:

P1dB out	24 dBm
Gain	>10 dB
Center Frequency f _c	29 GHz
Bandwidth	200 MHz

(2) Base Station PA

This will be used with modulation ranging from QPSK to 64 QAM and RRC filter with $\alpha = 0.15$ to 0.35:

P1dB out	30 dBm
Gain	>10 dB
Center Frequency f _c	29 GHz
Bandwidth	1 GHz

In both cases, the following parameters should be provided:

P1dB out	
Gain	
Output SNR	
Center Frequency f _c	
Bandwidth	
Efficiency	

and the following measurement data is requested:

Parameters	Conditions	Why is it important?
Gain	Small-signal (at f_c)	
P1dB	Input power at 1 dB compression (at f_c)	Required for system simulation
IP3	Two-tone result based on IM3 measurement (submission should specify the two frequencies)	tools using a polynominal model of the PA [1].

	AM-AM: dBm vs. dBm	Required for system simulation tools using a behavioral model of the PA [2].
AM-AM AM-PM	AM-PM: degrees vs. dBm Measure at f_c ; repeat at band edges.	Could also be used to find a Saleh-like formula that fits the conversion curves [4]; this is suitable for incorporation into common system simulation tools.

Small signal scattering parameters	At least 100 frequencies equally spaced across the specified bandwidth	System model can be improved [3] by taking into account the frequency dependence of the gain.
	ACPR= power in the upper or lower adjacent channel power in the main channel	To validate PA model using AM-AM and AM-PM data.
ACPR	Stimulate with QPSK, 16-QAM and 64- QAM, at Symbol Rate = 10 to 40 Mbaud and RRC filtered w/ ROF = 0.15, 0.25 and 0.35. In submission, specify conditions, including channels.	ACPR is a good linearity figure- of-merit for digital wireless system. Behavioral models simulate this figure, but measurements are still needed to see how good the model is.

Contributions that relate experience in simulating systems with the PA and comparing these simulation results with real life behavior are welcomed, as are suggested models and other comments.

Appendix

A nonlinear Power Amplifier (PA) model for 802.16 simulations should satisfy the following requirements:

- model must determine the signal envelope at the output of the PA given the input signal envelope (such a model could be used to predict, with a given input, the output spectrum, ACPR or other spectral regrowth figures, and EVM)
- model should be capable of taking into account the frequency dependence of the nonlinear response across the bandwidth, if such an effect is non-negligible
- the model parameters, including distortion parameters, must be externally measurable from real PAs.
- the model must not require a large amount of computation.

In order of presumed increasing accuracy, the models available are:

• Polynomial models [1]:

Gain compression is calculated according to a polynomial decomposition. The coefficients of this polynomial are determined by the amplifier linear gain, P1dB, and the third order intercept point (IP3); these parameters are commonly provided on data sheets. In general, since this model does not account for phase distortion in the envelope transfer function, it cannot accurately predict spectral regrowth.

• Behavioral models [2]:

The model parameters are the measured conversion curves, also known as AM-AM and AM-PM conversion.

• Frequency dependent models [3]:

If conversion curves happen to vary across the system's large band of operation, small-signal frequency response of the PA can be taken into account.
